CALCULATING THE SOFT FUNCTION

KEES BENKENDORFER

CONTENTS

1. SETUP

We wish to calculate the resolved soft function $S_R(\rho - z_{\text{cut}})$ which describes soft radiation which passes the groomer due to proximity to the resolved gluon. If the resolved emission occurs at an angle θ from the quark axis, then any radiation at smaller angles will pass the groomer. A schematic of this situation is displayed in Fig. 1.

The goal is to calculate the first-order term in an expansion of S_R. We can then use renormalization group evolution in conjunction with the other first-order results of functions in the factorization equation to achieve an all-orders calculation of the cross section.

Let the resolved gluon have momentum k_g, the quark lie along direction $n_q = (1, 0, 0, 1)$, and consider an extra-soft gluon with momentum k. If the extra-soft gluon is closer to the quark, then its dominant contribution to the jet mass ρ will come from its interaction with the quark:

$$\rho = \frac{4k^+}{Q} \tag{1}$$

where $k^{\pm} = k^0 \mp k_z$ are light-cone coordinates defined with respect to the quark axis. If the extra-soft gluon is closer to the resolved gluon, then its contribution to the jet mass from the quark interaction has already been accounted for in the contribution of the resolved gluon. The leading-order contribution from the new gluon therefore comes with its interaction with the resolved gluon. If n_g is the direction of the resolved gluon, then the contribution is

$$\rho = \frac{4k \cdot n_g}{Q} = \frac{4k \cdot k_g}{E_g Q} \tag{2}$$

with E_g the energy of the resolved gluon.

Notice that the angle between the extra-soft gluon and the quark is given by

$$1 - \cos\theta_{gq} = \frac{k^+}{k^0} \tag{3}$$

while the angle between the extra-soft gluon and the resolved gluon is

$$1 - \cos\theta_{gg} = \frac{k \cdot n_g}{k^0}. \tag{4}$$

FIGURE 1. Schematic head-on view of emissions according to the jet groomer. Radiation within the peanut-shaped region will pass the grooming algorithm.

The case in which the extra-soft gluon is closer to the quark is the case in which $\theta_{gq} < \theta_{gg}$, so $1 - \cos\theta_{gq} < 1 - \cos\theta_{gg}$ and, in turn $k^+ < k \cdot n_g$. Therefore, the total measurement function is

$$\delta_\rho = \Theta(k^+ - k \cdot n_g)\,\delta\left(\rho - \frac{4k^+}{Q}\right) + \Theta(k \cdot n_g - k^+)\,\delta\left(\rho - \frac{4k \cdot n_g}{Q}\right). \tag{5}$$

We also need to impose the kinematic constraint that the gluon is in the peanut-shaped region of Fig. 1. Saying that the gluon is in the region is equivalent to saying that it is not outside the region. The gluon is outside of the quark's radius of influence if

$$\frac{k^+}{k^0} = 1 - \cos\theta_{gq} > 1 - \cos\theta = n_g \cdot n_q. \tag{6}$$

On the other hand, the gluon is outside the resolved gluon's radius of influence if

$$\frac{k \cdot n_g}{k^0} = 1 - \cos\theta_{gg} > 1 - \cos\theta = n_g \cdot n_q. \tag{7}$$

Therefore, the grooming restriction is

$$\Theta_{\mathrm{mMDT}} = 1 - \Theta(k^+ - k^0 n_g \cdot n_q)\,\Theta(k \cdot n_g - k^0 n_g \cdot n_q). \tag{8}$$

The matrix element accounts for the possibility that the gluon be emitted from any pairs of resolved particles **[TODO: need to sort out prefactors, include color matrices. Also it's not actually a sum]**

$$|\mathcal{M}|^2 = \sum_{i<j} \frac{n_i \cdot n_j}{(n_i \cdot k)(n_j \cdot k)} \tag{9}$$

where i, j range over all pairs of resolved particles. Each term of the matrix element corresponds to a separate soft function. For now, we will focus on the first term

$$|\mathcal{M}_{q\bar{q}}|^2 = \frac{n_q \cdot n_{\bar{q}}}{(n_q \cdot k)(n_{\bar{q}} \cdot k)} = \frac{2}{k^+ k^-} \tag{10}$$

with $n_{\bar{q}} = (1, 0, 0, -1)$ the antiquark direction. **[TODO: need to handle other soft functions]**

Finally, phase space in d dimensions takes the usual form

$$d\Pi = \frac{d^d k}{(2\pi)^d} 2\pi\,\delta\big(k^2\big)\,\Theta(k^+)\,\Theta(k^- - k^+). \tag{11}$$

Notice that we are enforcing the gluon to be emitted in the hemisphere with the quark by requiring $k^- - k^+$. We will multiply the result at the end by a factor of 2 to account for the case where the gluons are emitted in the other hemisphere. Note that we are only scanning over the momentum of the extra-soft gluon: under the assumption that this gluon is softer than the resolved gluon, this emission does not influence the momentum of the quarks or resolved gluon.

Putting everything together, we find

$$S_R(\rho - z_{\text{cut}}) = 2 \int \frac{d^d k}{(2\pi)^{d-1}} \delta(k^2) \Theta(k^+) \Theta(k^- - k^+) \frac{2}{k^+ k^-}$$
$$\times \left[\Theta(k^+ - k \cdot n_g) \delta\left(\rho - \frac{4k^+}{Q}\right) + \Theta(k \cdot n_g - k^+) \delta\left(\rho - \frac{4k \cdot n_g}{Q}\right) \right] \quad (12)$$
$$\times \left[1 - \Theta(k^+ - k^0 n_g \cdot n_q) \Theta(k \cdot n_g - k^0 n_g \cdot n_q) \right].$$

2. COORDINATE CHOICE

Now we need to determine which coordinates in which to work. Notice that, physically, there is an axial symmetry to the problem: nothing depends on the angle of the resolved emission about the quark axis. Therefore, we might define our momenta in terms of their transverse momentum, pseudorapidity, and angle about the axis. To get from Cartesian (p_x, p_y, p_z) to this detector coordinate system $(p_\perp, \phi, \eta)$, we use the following transformations:

$$p_x = p_\perp \cos \phi \quad p_y = p_\perp \sin \phi \quad p_z = p_\perp \sinh \eta \quad p_0 = p_\perp \cosh \eta$$
$$p_\perp = \sqrt{p_x^2 + p_y^2} \quad \phi = \arctan\left(\frac{p_y}{p_x}\right) \quad \eta = \operatorname{arctanh}\left(\frac{p_z}{|\mathbf{p}|}\right). \quad (13)$$

Under this transformation, the extra-soft gluon has momentum

$$k = (k_0, k_\perp, \phi_k, \eta_k). \quad (14)$$

The resolved gluon is fixed in space from the perspective of the extra-soft gluon, so we can write it in whichever coordinates are convenient. Let us pick spherical coordinates, where the gluon momentum has an azimuthal angle ϕ_g and an angle θ_g from the jet axis

$$k_g = (k_0, r, \theta, \phi) = (E_g, E_g, \theta_g, \phi_g) \quad (15)$$

and hence direction vector

$$n_g = (1, 1, \theta_g, \phi_g). \quad (16)$$

Finally, without loss of generality, we can define our coordinate axis so that the resolved emission is at angle $\phi_g = 0$, thereby setting

$$k_g = (E_g, E_g, \theta_g, 0) \quad n_g = (1, 1, \theta_g, 0). \quad (17)$$

Now we can transform each term of Eq. 12. First, notice that

$$k^+ = k_0 - k_z = k_\perp (\cosh \eta_k - \sinh \eta_k) = k_\perp e^{-\eta_k}, \quad (18)$$

and similarly

$$k^- = k_\perp e^{\eta_k}. \quad (19)$$

Hence, the restriction $k^+ > 0$ becomes $k_\perp > 0$ and $k^- > k^+$ becomes $\eta_k > 0$. That is,

$$\Theta(k^+) \Theta(k^- - k^+) = \Theta(k_\perp) \Theta(\eta_k). \quad (20)$$

The first term in the matrix element is then simply

$$|\mathcal{M}|^2 = \frac{2}{k^+ k^-} = \frac{2}{k_\perp^2}. \quad (21)$$

Next comes the measurement function. First notice that (in Cartesian coordinates)

$$k \cdot n_g = (k_\perp \cosh \eta_k, k_\perp \cos \phi_k, k_\perp \sin \phi_k, k_\perp \sinh \eta_k) \cdot (1, \sin \theta_g, 0, \cos \theta_g)$$
$$= k_\perp [\cosh \eta_k - \cos \phi_k \sin \theta_g - \sinh \eta_k \cos \theta_g]. \quad (22)$$

Therefore

$$\Theta(k^+ - k \cdot n_g) = \Theta(\cos\phi_k \sin\theta_g - (1-\cos\theta_g)\sinh\eta_k)$$

$$= \Theta\left(\cos\phi_k \frac{\sin\theta_g}{1-\cos\theta_g} - \sinh\eta_k\right) \tag{23}$$

$$= \Theta\left(\cos\phi_k \cot\frac{\theta_g}{2} - \sinh\eta_k\right)$$

and

$$\Theta(k \cdot n_g - k^+) = \Theta\left(\sinh\eta_k - \cos\phi_k \cot\frac{\theta_g}{2}\right). \tag{24}$$

The full measurement function is then

$$\delta_\rho = \Theta\left(\cos\phi_k \cot\frac{\theta_g}{2} - \sinh\eta_k\right)\delta\left(\rho - \frac{4k_\perp e^{-\eta_k}}{Q}\right)$$

$$+ \Theta\left(\sinh\eta_k - \cos\phi_k \cot\frac{\theta_g}{2}\right)\delta\left(\rho - \frac{4k_\perp}{Q}[\cosh\eta_k - \cos\phi_k \sin\theta_g - \sinh\eta_k \cos\theta_g]\right). \tag{25}$$

Finally, we have the mMDT groomer. Notice that

$$\Theta\big(k^+ - k^0 n_g \cdot n_q\big) = \Theta(\cos\theta_g - \tanh\eta_k) \tag{26}$$

and

$$\Theta\big(k \cdot n_g - k^0 n_g \cdot n_q\big) = \Theta(\cot\theta_g - e^{\eta_k}\cos\phi_k). \tag{27}$$

Therefore,

$$1 - \Theta(k^+ - k^0 n_g \cdot n_q)\,\Theta(k \cdot n_g - k^0 n_g \cdot n_q) = 1 - \Theta(\cos\theta_g - \tanh\eta_k)\,\Theta(\cot\theta_g - e^{\eta_k}\cos\phi_k). \tag{28}$$

Putting everything together so far, we have

$$S_R = 2\int \frac{d^d k}{(2\pi)^{d-1}} \delta(k^2)\,\Theta(k_\perp)\,\Theta(\eta_k)\,\frac{2}{k_\perp^2}$$

$$\times \left[\Theta\left(\cos\phi_k \cot\frac{\theta_g}{2} - \sinh\eta_k\right)\delta\left(\rho - \frac{4k_\perp e^{-\eta_k}}{Q}\right)\right.$$

$$+ \Theta\left(\sinh\eta_k - \cos\phi_k \cot\frac{\theta_g}{2}\right)\delta\left(\rho - \frac{4k_\perp}{Q}[\cosh\eta_k - \cos\phi_k \sin\theta_g - \sinh\eta_k \cos\theta_g]\right)\bigg]$$

$$\times [1 - \Theta(\cos\theta_g - \tanh\eta_k)\,\Theta(\cot\theta_g - e^{\eta_k}\cos\phi_k)]. \tag{29}$$

The last thing to evaluate is the phase space measure. We wish to convert

$$dk_0 dk_z\, d^{d-2}k_\perp\, \delta(k^2) \to dk_0 d\eta_k\, d^{d-2}dk_\perp\, \delta(k^2) \tag{30}$$

where $k_\perp$ represents the off-axis components of k in $d-2$ dimensions. With $d = 4 - 2\epsilon$, we can write this in spherical coordinates as   **Overcounting angles... should be d-3?**

$$d^{d-2}k_\perp = k_\perp^{d-3}dk_\perp\,\sin^{-2\epsilon}\phi_k\,d\phi_k\,d\Omega_{d-2} \tag{31}$$

with Ω_{d-2} the solid angle of the $d-2$ dimensional sphere. Integrating over this solid angle yields [1]

$$\int d\Omega_{d-2} = \frac{2\pi^{(d-2)/2}}{\Gamma(\frac{d-2}{d})} = \frac{2\pi^{1-\epsilon}}{\Gamma(1-\epsilon)}. \tag{32}$$

Thus, we find that

$$d^{d-2}k_\perp = dk_\perp d\phi_k\, k_\perp^{d-3} \sin^{-2\epsilon}\phi_k\,\frac{2\pi^{1-\epsilon}}{\Gamma(1-\epsilon)}. \tag{33}$$

Now also notice that

$$\delta(k^2) = \delta\big(k_0^2 - k_\perp^2 - k_z^2\big) = \delta\big(k_0^2 - k_\perp^2 \cosh^2 \eta_k\big). \tag{34}$$

This simplifies to

$$\delta\big(k_0^2 - k_\perp^2 \cosh^2 \eta_k\big) = \frac{1}{2k_\perp \cosh \eta_k} \delta(k_0 - k_\perp \cosh \eta_k). \tag{35}$$

Therefore, we can integrate out k_0 (notice that we have sneakily already applied the delta function where k_0 appeared earlier):

$$\int dk_0 \delta(k^2) = \frac{1}{2k_\perp \cosh \eta_k}. \tag{36}$$

Finally, we need to account for the Jacobian in the (k_0, k_z) transformation **[is it correct to only account for this portion of the transformation which we haven't yet considered?]**:

$$\frac{\partial(k_0, k_z)}{\partial(k_0, \eta_k)} = \begin{pmatrix} 1 & 0 \\ 0 & k_\perp \cosh \eta_k \end{pmatrix}. \tag{37}$$

The standard Jacobian factor is then the determinant (in absolute value)

$$dk_0 dk_z = k_\perp \cosh \eta_k \, dk_0 d\eta_k. \tag{38}$$

All together, the phase space measure is

$$
\begin{aligned}
\int \frac{d^d k}{(2\pi)^{d-1}} \delta(k^2) &= \frac{\pi^{1-\epsilon}}{(2\pi)^{3-2\epsilon}\Gamma(1-\epsilon)} \int dk_\perp d\phi_k d\eta_k \, k_\perp^{-1-2\epsilon} \sin^{-2\epsilon} \phi_k \\
&= \frac{(4\pi)^\epsilon}{8\pi^2 \Gamma(1-\epsilon)} \int dk_\perp d\phi_k d\eta_k \, k_\perp^{-1-2\epsilon} \sin^{-2\epsilon} \phi_k.
\end{aligned} \tag{39}
$$

Under the modified minimal subtraction scheme, we will set $(4\pi)^\epsilon \to 1$ (and will also set $\gamma_E \to 0$ as it comes up). The full integral is now

$$
\begin{aligned}
S_R = \frac{1}{2\pi^2 \Gamma(1-\epsilon)} \int dk_\perp d\phi_k d\eta_k \, &k_\perp^{-1-2\epsilon} \sin^{-2\epsilon} \phi_k \, \Theta(k_\perp)\Theta(\eta_k) \\
\times \Bigg[&\Theta\bigg(\cos\phi_k \cot\frac{\theta_g}{2} - \sinh\eta_k\bigg) \delta\bigg(\rho - \frac{4k_\perp e^{-\eta_k}}{Q}\bigg) \\
+ &\Theta\bigg(\sinh\eta_k - \cos\phi_k \cot\frac{\theta_g}{2}\bigg) \delta\bigg(\rho - \frac{4k_\perp}{Q}[\cosh\eta_k - \cos\phi_k \sin\theta_g - \sinh\eta_k \cos\theta_g]\bigg)\Bigg] \\
\times [1 - &\Theta(\cos\theta_g - \tanh\eta_k)\,\Theta(\cot\theta_g - e^{\eta_k}\cos\phi_k)].
\end{aligned} \tag{40}
$$

3. EVALUATING THE INTEGRAL

Let us first evaluate the integral when

$$\cos\phi_k \cot\frac{\theta_g}{2} > \sinh\eta_k. \tag{41}$$

In this scenario, the measurement delta function transforms as

$$\delta\bigg(\rho - \frac{4k_\perp e^{-\eta_k}}{Q}\bigg) = \frac{Qe^{\eta_k}}{4}\delta\bigg(k_\perp - \frac{\rho Q e^{\eta_k}}{4}\bigg). \tag{42}$$

Then we can integrate out $k_\perp$ to find

$$
\begin{aligned}
S_R^I = \frac{1}{2\pi^2 \Gamma(1-\epsilon)} \frac{1}{\rho^{1+2\epsilon}} \bigg(\frac{Q}{4}\bigg)^{-2\epsilon} \int d\phi_k d\eta_k \, &e^{-2\epsilon\eta_k} \sin^{-2\epsilon} \phi_k \, \Theta(\eta_k)\Theta\bigg(\cos\phi_k \cot\frac{\theta_g}{2} - \sinh\eta_k\bigg) \\
\times [1 - &\Theta(\cos\theta_g - \tanh\eta_k)\Theta(\cot\theta_g - e^{\eta_k}\cos\phi_k)].
\end{aligned} \tag{43}
$$

Only need to worry about eps^-1 and lower overall, so order eps^0;
this integral does not diverge, so can set eps = 0

To evaluate this further, we can first expand all available terms in ϵ:

$$e^{-2\epsilon\eta_k}\sin^{-2\epsilon}\phi_k = 1 - 2\epsilon(\eta_k + \log\sin\phi_k) + \mathcal{O}(\epsilon^2), \tag{44}$$

which yields (focusing just on the integral now)

$$I = \int d\phi_k d\eta_k \left[1 - 2\epsilon(\eta_k + \log\sin\phi_k) + \mathcal{O}(\epsilon^2)\right]\Theta(\eta_k)\Theta\left(\cos\phi_k\cot\frac{\theta_g}{2} - \sinh\eta_k\right)$$
$$\times\left[1 - \Theta(\cos\theta_g - \tanh\eta_k)\Theta(\cot\theta_g - e^{\eta_k}\cos\phi_k)\right] \tag{45}$$

where I is the value of the integral at hand. To simplify expressions, let $\xi = \cot(\theta_g/2)$. Now, notice that the resolved gluon is at a wide angle, so if the extra-soft gluon is near the resolved gluon, we must have $\eta_k \ll 1$ **[is this legit? seems sketchy]**. Expanding to lowest order in η_k we find

$$I = \int d\phi_k d\eta_k \left[1 - 2\epsilon\log\sin\phi_k + \mathcal{O}(\epsilon^2) + \mathcal{O}(\eta_k)\right]\Theta(\eta_k)\Theta(\xi\cos\phi_k - \eta_k)$$
$$\times\left[1 - \Theta(\cos\theta_g - \eta_k)\Theta(\cot\theta_g - \cos\phi_k)\right] \tag{46}$$

[this seems super sketchy]. The first term then yields

$$\int_{-\pi}^{\pi} d\phi_k \int_0^{\xi\cos\phi_k} d\eta_k[1 - 2\epsilon\log\sin\phi_k] = 0 \tag{47}$$

[uh-oh]. To evaluate the second term, notice that we now require $\eta_k < \cos\theta_g$ and $\cos\phi_k < \cot\theta_g$. We already have the requirement that $\eta_k < \xi\cos\phi_k$. The restriction for η_k is therefore dependent on the value of ϕ_k:

$$\Theta(\xi\cos\phi_k - \eta_k)\Theta(\cos\theta_g - \eta_k)\Theta(\cot\theta_g - \cos\phi_k) = \Theta(\cot\theta_g - \cos\phi_k)$$
$$\times\left[\Theta(\cos\theta_g - \xi\cos\phi_k)\Theta(\xi\cos\phi_k - \eta_k)\right.$$
$$\left. + \Theta(\xi\cos\phi_k - \cos\theta_g)\Theta(\cos\theta_g - \eta_k)\right]. \tag{48}$$

Now notice that $\cos\theta_g/\xi = \cos\theta_g\tan(\theta_g/2)$, so we have

$$\Theta(\xi\cos\phi_k - \eta_k)\Theta(\cos\theta_g - \eta_k)\Theta(\cot\theta_g - \cos\phi_k) = \Theta(\cot\theta_g - \cos\phi_k)$$
$$\times\left[\Theta\left(\cos\theta_g\tan\frac{\theta_g}{2} - \cos\phi_k\right)\Theta(\xi\cos\phi_k - \eta_k)\right.$$
$$\left. + \Theta\left(\cos\phi_k - \cos\theta_g\tan\frac{\theta_g}{2}\right)\Theta(\cos\theta_g - \eta_k)\right]. \tag{49}$$

Moreover, for $0 < \theta_g < \pi/2$, we know that

$$\cot\theta_g > \cos\theta_g\tan\frac{\theta_g}{2}, \tag{50}$$

so the bounds simplify to

$$\Theta(\xi\cos\phi_k - \eta_k)\Theta(\cos\theta_g - \eta_k)\Theta(\cot\theta_g - \cos\phi_k) = \Theta\left(\cos\theta_g\tan\frac{\theta_g}{2} - \cos\phi_k\right)\Theta(\xi\cos\phi_k - \eta_k)$$
$$+ \Theta(\cot\theta_g - \cos\phi_k)\Theta\left(\cos\phi_k - \cos\theta_g\tan\frac{\theta_g}{2}\right)\Theta(\cos\theta_g - \eta_k). \tag{51}$$

The first integral is

$$\int d\phi_k d\eta_k [1 - 2\epsilon \log \sin \phi_k] \Theta(\eta_k) \Theta\left(\cos \theta_g \tan \frac{\theta_g}{2} - \cos \phi_k\right) \Theta(\xi \cos \phi_k - \eta_k)$$

$$= \int_{-\pi}^{\pi} d\phi_k \, \xi \cos \phi_k [1 - 2\epsilon \log \sin \phi_k] \Theta\left(\cos \theta_g \tan \frac{\theta_g}{2} - \cos \phi_k\right) \quad (52)$$

$$= \xi \sqrt{1 - \beta^2} \left[1 + 2\epsilon - \epsilon \log\left(1 - \beta^2\right)\right]$$

with

$$\beta \equiv \cos \theta_g \tan \frac{\theta_g}{2}. \quad (53)$$

The second integral is

$$\int d\phi_k d\eta_k [1 - 2\epsilon \log \sin \phi_k] \Theta(\eta_k) \Theta(\cot \theta_g - \cos \phi_k) \Theta(\cos \phi_k - \beta) \Theta(\cos \theta_g - \eta_k)$$

$$= \cos \theta_g \int_{-\pi}^{\pi} d\phi_k [1 - 2\epsilon \log \sin \phi_k] \Theta(\cot \theta_g - \cos \phi_k) \Theta(\cos \phi_k - \beta)$$

$$= \cos \theta_g \left[\phi_k + \epsilon \left[2\phi_k \log\left(\frac{1 - e^{2i\phi_k}}{\sin \phi_k}\right) - i\left(\phi_k^2 + \mathrm{Li}_2 e^{2i\phi_k}\right)\right]\right]\Big|_{\phi_k = \arccos \beta}^{\arccos \cot \theta_g}$$

$$= \cos \theta_g \left[\phi_k + \epsilon \left[2\phi_k \log\left(-2ie^{i\phi_k}\right) - i\left(\phi_k^2 + \mathrm{Li}_2 \, e^{2i\phi_k}\right)\right]\right]\Big|_{\phi_k = \arccos \beta}^{\arccos \cot \theta_g}$$

$$= \cos \theta_g \left[\phi_k + \epsilon \left[\phi_k \log 4 + 2i\phi_k^2 - i\left(\phi_k^2 + \mathrm{Li}_2 e^{2i\phi_k}\right)\right]\right]\Big|_{\phi_k = \arccos \beta}^{\arccos \cot \theta_g} \quad (54)$$

$$= \cos \theta_g \left[\phi_k + \epsilon \left[\phi_k \log 4 + i\phi_k^2 - i\mathrm{Li}_2 \, e^{2i\phi_k}\right]\right]\Big|_{\phi_k = \arccos \beta}^{\arccos \cot \theta_g}$$

$$= \cos \theta_g \left[\arccos \cot \theta_g - \arccos\left(\cos \theta_g \tan \frac{\theta_g}{2}\right)\right]$$

$$+ \epsilon \cos \theta_g \log 4 \left[\arccos \cot \theta_g - \arccos\left(\cos \theta_g \tan \frac{\theta_g}{2}\right)\right]$$

$$+ i\epsilon \cos \theta_g \left[\arccos^2 \cot \theta_g - \arccos^2\left(\cos \theta_g \tan \frac{\theta_g}{2}\right)\right]$$

$$- i\epsilon \cos \theta_g \left[\mathrm{Li}_2 \, e^{2i \arccos \cot \theta_g} - \mathrm{Li}_2 \, e^{2i \arccos \left(\cos \theta_g \tan(\theta_g/2)\right)}\right]$$

where Li_n is the polylogarithm function. Putting everything together, the full value of the integral is

$$I = -\cot \frac{\theta_g}{2} \sqrt{1 - \cos^2 \theta_g \tan^2 \frac{\theta_g}{2}} \left[1 + 2\epsilon - \epsilon \log\left(1 - \cos^2 \theta_g \tan^2 \frac{\theta_g}{2}\right)\right]$$

$$- \cos \theta_g \left[\arccos \cot \theta_g - \arccos\left(\cos \theta_g \tan \frac{\theta_g}{2}\right)\right]$$

$$- \epsilon \cos \theta_g \log 4 \left[\arccos \cot \theta_g - \arccos\left(\cos \theta_g \tan \frac{\theta_g}{2}\right)\right] \quad (55)$$

$$- i\epsilon \cos \theta_g \left[\arccos^2 \cot \theta_g - \arccos^2\left(\cos \theta_g \tan \frac{\theta_g}{2}\right)\right]$$

$$+ i\epsilon \cos \theta_g \left[\mathrm{Li}_2 \, e^{2i \arccos \cot \theta_g} - \mathrm{Li}_2 \, e^{2i \arccos \left(\cos \theta_g \tan(\theta_g/2)\right)}\right].$$
